BASIC ABSTRACT:

WO 2005028181 A1 UPAB: 20051222
NOVELTY - The angular velocity of motor for driving screw in forward direction, is obtained using output of an encoder that detects the rotating angle of the motor. The resin pressure value is estimated from the angular velocity of motor using
specified observer theorem. The motor is controlled based on the torque instruction value calculated from the estimated resin pressure value.
DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for pressure control apparatus.
USE - For controlling resin injection pressure in electrically driven injection molding machine.
ADVANTAGE - Enables controlling resin injection pressure accurately, without using pressure detector such as load cell. DESCRIPTION OF DRAWINGS - The figure shows the block diagram of the control circuit of the injection molding machine. (Drawing includes non-English language text).

BASIC ABSTRACT:

DE 10218736 A1 UPAB: 20060120

NOVELTY - The regulation method detects the combustion chamber pressure within an engine cylinder (2) in dependence on the crank angle of the crankshaft (4) controlling the movement of the reciprocating piston (3), with derivation of a corresponding engine torque, combined with the angular velocity of the crankshaft for providing the effective engine torque, used for regulation of at least one operating parameter of the engine (1).

DETAILED DESCRIPTION - An INDEPENDENT CLAIM for a regulating device for a diesel engine is also included.

USE - The regulation method is used for regulating at least one operating parameter of a diesel engine.

ADVANTAGE - Regulation is effected in dependence on effective engine torque.

DESCRIPTION OF DRAWINGS - The figure shows a schematic representation of a diesel engine cylinder incorporating detection of the combustion chamber pressure. Engine (1)

BASIC ABSTRACT:

JP 2001201300 A UPAB: 20050526

NOVELTY - A pitch/yawing control section (3) controls the deviation of missile based on its acceleration and roll angular velocity. A calculation unit (11) detects guiding roll movement of the tail wing from the steering angle of head side wing, based on dynamic pressure and output of roll control calculation unit. The power steering system (6) controls the control section based on the steering angle of head side and tail wing rolls movement.

USE - Guided missile.

ADVANTAGE - Increases stability and reduces aerodynamic load torque as the tail wing is guided based on steering angle of head side wing. Improves reliability as the control of guided missile does not require additional components. DESCRIPTION OF DRAWINGS - The figure shows the guided missile control system. (Drawing includes non-English language text).

BASIC ABSTRACT:

JP 11090518 A UPAB: 20050521

NOVELTY - The time lag of control system signal operation route is observed by a state prediction device of a controller (21). The manipulation variable of the rolling mill operation controllers is output, after compensating the time lag, by the controller based on the calculated estimation result of the variable state of rolling mill. DETAILED DESCRIPTION - The exit thickness, the tension between the rolling stands and the louver are detected and an universal set of variable states of the exit thickness deviation, a louver angle deviation, the louver angular velocity deviation, the deviation of the tension between the stands, the deviation of plate velocity between the stands and the louver torque deviation is estimated. The controller (21) calculates the manipulation variables and after compensating with the time lag factor, inputs a louver torque setting (16), a mill velocity setting (17) and the standard position setting (15) to a louver motor torque controller (19), a mill motor speed controller (20) and a stand pressure position controller (18), respectively, and controls the operation of the rolling mill and obtains the desired value of the exit thickness, the tension between the stands and the louver angle.

USE - For controlling operation of continuous hot rolling mill for compensating time lag.

ADVANTAGE - Obtains robust control of continuous hot rolling mill. Improves product accuracy by preventing control system time lag influencing the mill operation. Improves the production. DESCRIPTION OF DRAWING(S) - The drawing provides a block diagram of controller in detail. (15) Stand position setting unit; (16) Louvre torque setting input; (17) Mill setting unit; (18) Stand pressure position controller; (19) Louvre motor torque controller; (20) Mill motor speed controller; (21) Controller.

DOCUMENTATION ABSTRACT:

USE

For controlling operation of continuous hot rolling mill for compensating time lag.

ADVANTAGE

Obtains robust control of continuous hot rolling mill. Improves product accuracy by preventing control system time lag influencing the mill operation. Improves the production.

NOVELTY

The time lag of control system signal operation route is observed by a state prediction device of a controller (21). The manipulation variable of the rolling mill operation controllers is output, after compensating the time lag, by the controller based on the calculated estimation result of the variable state of rolling mill.

DETAILED DESCRIPTION

The exit thickness, the tension between the rolling stands and the louver are detected and an universal set of variable states of the exit thickness deviation, a louver angle deviation, the louver angular velocity deviation, the deviation of the tension between the stands, the deviation of plate velocity between the stands and the louver torque deviation is estimated. The controller (21) calculates the manipulation variables and after compensating with the time lag factor, inputs a louver torque setting (16), a mill velocity setting (17) and the standard position setting (15) to a

louver motor torque controller (19), a mill motor speed controller (20) and a stand pressure position controller (18), respectively, and controls the operation of the rolling mill and obtains the desired value of the exit thickness, the tension between the stands and the louver angle.

DESCRIPTION OF DRAWING(S)

The drawing provides a block diagram of controller in detail.

(15) Stand position setting unit
(16) Louvre torque setting input
(17) Mill setting unit
(18) Stand pressure position controller
(19) Louvre motor torque controller

IPC RECLASSIF.: B29C0045-77 [I,A]; B29C0045-77 [I,C]
BASIC ABSTRACT:

JP 09220748 A UPAB: 20050519 In a method of indicating a resin injection pressure on an electric motor driven injection moulding machine having a screw (6), an electric motor (1) for driving the screw in an injection direction and an indicating unit (14) for indicating an injection pressure, the wave of a load torque (T L) of the electric motor obtainable under the following formulae is indicated when the resin injection pressure is indicated on the indicating unit:

T L = i/ KT - J . d ω /dt (T L : load torque of electric motor) i : Torque current of electric motor K T : Torque constant J : Moment of inertia of the whole of injection moulding machine ω : Angular velocity of electric motor.

Also claimed is an appts. for indicating resin injection pressure, which comprises a current detecting. means (15) for detecting a current of the electric motor (1) , a position detecting means (13) for detecting the position of the electric motor and a controller (11), which calculates a

torque current (i) of the electric motor on the basis of a signal detected by the current detecting means (15) as well as an angular velocity of the motor (1) on the basis of a signal detected by the position detecting means (13) and indicates on an indicating unit (14) a load torque (T L) of the motor (1) obtainable under the above-mentioned formulae.
ADVANTAGE - Capable of eliminating the appearance of a wave (H) at the start of the injection and indicating a needed injection pressure only, correctly establishing the moulding requirements such as the injection pressure, the heating temperature of the injection cylinder and the temperature of the molten resin by reference to the injection pressure.

DOCUMENTATION ABSTRACT:

JP9220748

In a method of indicating a resin injection pressure on an electric motor driven injection moulding machine having a screw (6), an electric motor (1) for driving the screw in an injection direction and an indicating unit (14) for indicating an injection pressure, the wave of a load torque (T L) of the electric motor obtainable under the following formulae is indicated when the resin injection pressure is indicated on the indicating unit:

T L = i/ KT - J . d ω /dt (T L : load torque of electric motor) i : Torque current of electric motor K T : Torque constant J : Moment of inertia of the whole of injection moulding machine ω : Angular velocity of electric motor.

Also claimed is an appts. for indicating resin injection pressure, which comprises a current detecting. means (15) for detecting a current of the electric motor (1) , a position detecting means (13) for detecting the position of the electric motor and a controller (11), which calculates a torque current (i) of the electric motor on the basis of a signal detected by the current detecting means (15) as well as an angular velocity of the motor (1) on the basis of a signal detected by the position detecting means (13) and indicates on an indicating unit (14) a load torque (T L) of the motor (1) obtainable under the above-mentioned formulae.

ADVANTAGE

Capable of eliminating the appearance of a wave (H) at the start of the injection and indicating a needed injection pressure only, correctly establishing the moulding requirements such as the injection pressure, the heating temperature of the injection cylinder and the temperature of the molten resin by reference to the injection pressure.

BASIC ABSTRACT:
JP 08207791 A UPAB: 20050513 The steering appts. has an angle sensor (16) which detects the angle turned by a steering wheel (1) and a steering wheel controller (14) which calculates the angular velocity of the wheel from this detected signal. According to the calculated angular velocity, the corresponding value of the steering rigidity is selected from the graph in which steering rigidity is started against the angular velocity. According to this steering rigidity, the instruction currently supplied from the controller to a pressure control valve (13) is calculated .
ADVANTAGE - Ensures steering stability and good steering response.

BASIC ABSTRACT:

JP 07310812 A UPAB: 20050511 The control method involves calculating presumed value of I/O torque of an engine based on the angular velocity of a throttle valve along the input axis (3). The I/O torque is determined from a performance diagram of the engine and a hydraulic torque converter (2). The change in angular velocity of a clutch which rotates along with an engagement part, is determined along the output axis (8). The transmission torque and the I/O torque of the clutch are found based on state equations of automatic transmission. The rotary change of the clutch along the output axis is calculated. The presumed value of the torque along the output axis is determined based on the calculated rotary change. A feedback control part determines the difference between the presumed and ideal torque values and contacts the oil pressure between the engagement part and the clutch. The feedback oil pressure is adjusted to approach target torque values. ADVANTAGE - Reduces shocks owing to velocity change. Optimizes control.

BASIC ABSTRACT:
EP 115291 A UPAB: 20050421 A machine (1) such as an alternator is driven e.g. by a triple-expansion turbine having a high-pressure stage (3), an intermediate-pressure stage (4) and two low- pressure stages (5,6). The high-pressure head (3) is supplied with fluid through a servo valve (7) and its instantaneous angular velocity is measured by a first detector (8). A second detector (9) measures the instantaneous angular velocity of the alternator (1).
The two detector outputs are decoded (10) to produce a signal representing the momentary angle of twist between the two shafts, and other signals representing their differences in speed and acceleration. Damage is calculated from the differentiated angular velocity detectoroutputs and the derivative of a servo valve travel signal.
ADVANTAGE - Accuracy is improved without recourse to special expensive current and voltage transformers.

BASIC ABSTRACT:
FR 2431642 A UPAB: 20050816 The circuit minimises the torsional vibration set up in the various gear shafts when disengaging gears, due to the energy stored in these shafts when driven. The circuitry is limited to 'kick-down-gear changes and small ratio gear changes, i.e. from first to second or second to third especially where the vehicle is moving down as steep slope.
Gear changes are made in three steps: simultaneous cutting of fuel injection, motor braking, de-clutching and gear disengagement; reengaging the clutch, cancellation of the dead point control; and calculation of the approach of synchronism, i.e. ratio of gear box input and output angular velocities.
Declutching occurs when the motor couple is half the maximum value.

ABSTRACT:
The invention relates to a numerical-control screw rod injection machine and a numerical control method thereof. The numerical control method includes inputting operation data, and controlling operation of switched reluctance motor by calculation of industrial-control microcomputer according to data from input equipment so as to drive screw rod injection machine. In the invention, the switched reluctance motor is driven to numerically control angular displacement and angular velocity of motor, which simplifies structure of screw rod injection machine greatly. The inventive numerical-control screw rod injection machine has the advantages of stepless regulation and control, good stability, simple structure, low cost, and high efficiency.

ABSTRACT: A rotary reform machine has a pair of reform wheels, which are rotatably driven to profile the extrudate while matching the output speed of extrudate exiting from the extrusion die of a plastics extruder. The wheels have equal diameters and are motor driven at the same angular velocity so that forming dies in the wheels synchronise and cooperate to pressure mould spaced sections of the extrudate feeding therethrough to form high quality end corners with an offal section therebetween. A haul-off pulls the strips from the extruder die, the rotary reform machine, a water trough and flash trimmer and into a cutter where the offal is removed. The strip is maintained under a predetermined tension load by use of an adjustable friction brake on the stabiliser foil so that the heated plastics exiting the extruder is uniform in initial profile, providing high quality extrudate feeding into the reforming wheels. ABSTRACT: The screw rotors for superchargers were manufactured with chopped carbon fibre epoxy composite screw rotors were tested in different combinations such as the male composite and female composite rotors, the male aluminium and female composite rotors. Temperature and pressure increases of the air at the outlet and the required torque of the supercharger were measured with respect to the angular velocities. 11 refs. SECONDARY: G05D003-12
ABSTRACT:
PROBLEM TO BE SOLVED: To provide a molding takeout device including an arm to be moved by the rotation of the motor shaft when a motor is put in operation, wherein the residual vibration of the arm can be suppressed as much as practicable even when the operation is conducted with the gain of a servo control device heightened. SOLUTION: The molding takeout device includes the arm 14, motor 2 having the shaft 1 for moving the arm 14, an angular velocity sensing means (encoder 3 and velocity calculation part 9) to sense the angular velocity of the motor 2, and the servo control device 11 furnished with a current controller 7 and a shaft torque presuming means 8 to presume the actually generated torque on the shaft 1, wherein the shaft torque presuming means 8 takes in the output signal from the angular velocity sensing means and the motor drive current iq as the input signal to the motor 2 and presumes the shaft torque generated on the shaft 1 on the basis of the two signals while the servo control device 11 makes negative feedback of the output from the presuming means 8 to the current controller 7.

ABSTRACT:

PROBLEM TO BE SOLVED: To reduce a sense of incompatibility for a travel characteristic and the deterioration of travel fuel consumption by setting the maximum limit value of the target torque of an engine based on the atmospheric state in the engine controlling the pressure of a continuously variable transmission based on the continuously variable transmission transfer torque calculated from the target torque.

SOLUTION: During an engine operation, an ECU 30 determines the normal target torque of an engine 10 with no atmospheric state considered by dividing the target output based on the depression quantity of an accelerator pedal 36 with the present angular velocity of the engine 10. The ECU 30 then calculates the atmospheric correction coefficient in the atmospheric state around an engine, adds frictional loss torque to the standard atmospheric maximum torque determined based on the present engine revolving speed, multiplying it by the atmospheric correction coefficient, and subtracting the frictional loss torque to determine the maximum limit of the target torque in the atmospheric state at that time. When the maximum limit torque is smaller than the target torque, the target torque is established in place of the maximum limit torque.
